Abstract

The term HbA1c refers to glycated haemoglobin. It develops when haemoglobin, a protein within red blood cells that carries oxygen throughout your body, joins with glucose in the blood, becoming ‘glycated’. By measuring glycated haemoglobin (HbA1c), clinicians are able to get an overall picture of what our average blood sugar levels have been over a period of weeks/months. For people with diabetes this is important as the higher the HbA1c, the greater the risk of developing diabetes-related complications. When the body processes sugar, glucose in the bloodstream naturally attaches to haemoglobin. The amount of glucose that combines with this protein is directly proportional to the total amount of sugar that is in your system at that time.

Keywords: HbA1C, proteinuria, diabetes mellitus

Introduction

Diabetic nephropathy occurs in as many as 30% of insulin dependent diabetes mellitus patients and 25% of noninsulin-dependent diabetes mellitus patients. Diabetic nephropathy is a dreaded disease with progressive and continuous. Deterioration in glomerular function resulting in irreversible renal failure. Diabetic nephropathy is an important cause of morbidity and mortality and is now among the most common cause of end-stage renal disease. However, there is an early phase of diabetic renal disease called incipient diabetic nephropathy. This study is intended to study the association of Proteinuria with HbA1C in Diabetes Mellitus. The knowledge of diabetes dates back to centuries before Christ. Polyuria disease resembling diabetes was described as early as 150 BC in ancient Egyptian records discovered by George Beers. Celsius (30BC-50AD) had recognised the disease. Diabetes, a Greek term, which literally means to ‘run thru’ or a ‘siphon’ was initially used by Aretaeus in first century AD for the generic description of a condition causing increased urine output. Roman physicians thought of diabetes as a “wonderful affection”, not very frequent among men being melted down of flesh and limbs into urine. The patient never stopped making water, but the flow is incessant as if from an opening of aqueducts Aretaeus, the Cappadocia [1, 2]

Because red blood cells in the human body survive for 8-12 weeks before renewal, measuring glycated haemoglobin (or HbA1c) can be used to reflect average blood glucose levels over that duration, providing a useful longer-term gauge of blood glucose control. If your blood sugar levels have been high in recent weeks, your HbA1c will also be greater. Two large-scale studies – the UK Prospective Diabetes Study (UKPDS) and the Diabetes Control and Complications Trial (DCCT) – demonstrated that improving HbA1c by 1% (or 11 mmol/mol) for people with type 1 diabetes or type 2 diabetes cuts the risk of microvascular complications by 25%.

Aims and Objectives

To study the association of Proteinuria with HbA1C in Diabetes Mellitus.

Materials and Methods

- Design: Cross-sectional design.
- Study population and setting: 60 patients admitted in the general medicine wards.
The study was done from Nov 2019 to March 2020 in the Department of Pathology, Kanachur Institute of Medical Sciences, Mangalore.

Inclusion criteria
1. Age: 18-80 years.
2. Those who gave written informed consent.

Exclusion criteria
1. Patients unwilling and uncooperative for the study
2. Patients suffering from known kidney pathology.
   - **Sampling method:** Convenience sampling.
   - **Study duration:** 6 months.

Results

Table 1: Age and Sex Distribution

<table>
<thead>
<tr>
<th>Mean Age</th>
<th>Std Deviation</th>

Discussion

Microvascular complications include
- Retinopathy
- Neuropathy
- Diabetic nephropathy (kidney disease)

Research has also shown that people with type 2 diabetes who reduce their HbA1c level by 1% are: [1]
- 19% less likely to suffer cataracts
- 16% less likely to suffer heart failure
- 43% less likely to suffer amputation or death due to peripheral vascular disease.

This study is intended to study the association of Proteinuria with HbA1C in Diabetes Mellitus. Several major studies among diabetics have been undertaken (Tuft et al 1956, Farqahar et al 1959, Gallman et al 1959, Hatch et al 1961, O Sullivan et al, Thomsal) and proteinuria especially when diffuse changes are considered on the whole advanced clinical diseases accompanied by severe glomerular lesions [3] In 1963, Keen and Chlouvervakis developed sensitive and specific radioimmunoassay for detecting human albumin in low concentration, i.e. proteinuria, which indicate earliest stage of diabetic renal disease. Later various other methods were developed for detection of proteinuria. [4] This means significant increase in Albumin Excretion Rate (AER). Albumin excretion in healthy individuals ranges from 1.5 to 20 mcg/min. with geometric mean in the range of 6.5 mcg/min., these have been termed norm albuminuria. Proteinuria thus defines the wide substantial range of albumin hypersecretion ranging between 20- to 200- mcg/min. (30 to 300 mg/day), Normal persons excrete less than 30 mg/day. Proteinuria is not detected by reagent sticks for urinary protein, which generally becomes positive only when proteinuria is greater than 550 mg/day. This degree of leakage is termed macroalbuminuria. [6] In contrast to microproteinuria, the degree of macroproteinuria shows no relationship with current level of diabetic control. Neither the mean plasma glucose concentration nor glycosylated haemoglobin levels correlated significantly with clearance and excretion rates of different proteins. Long-term correction of hyperglycaemia by an intensified treatment regimens failed to stop or significantly slow the progressive increase in fractional clearance of albumin and IgG in insulin-dependent diabetic subjects with renal failure over a period of 2 years observation. [7] In IDDM patients with low levels of proteinuria (i.e., AER of 20-30 mcg/min.), no consistent glomerular abnormalities have been found. Above these levels of urinary albumin excretion, however, the fractional volume of mesangium is on average significantly increased and minor reduction in creatinine clearance and rise in blood pressure are observed. Similar findings have been reported in NIDDM patients with proteinuria and proteinuria. [8]

Conclusion

A Strong association was found between HbA1C and Proteinuria.
